the growth in the field of digital signal processing began with the simulation of continuous time systems in the 1950s even though the origin of the field can be traced back to 400 years when methods were developed to solve numerically problems such as interpolation and integration during the last 40 years there have been phenomenal advances in the theory and application of digital signal processing in many applications the representation of a discrete time signal or a sys tem in the frequency domain is of interest to this end the discrete time fourier transform dtft and the z transform are often used in the case of a discrete time signal of finite length the most widely used frequency domain representation is the discrete fourier transform dft which results in a finite length sequence in the frequency domain the dft is simply composed of the samples of the dtft of the sequence at equally spaced frequency points or equivalently the samples of its z transform at equally spaced points on the unit circle the dft provides information about the spectral contents of the signal at equally spaced discrete frequency points and thus can be used for spectral analysis of signals various techniques commonly known as the fast fourier transform fft algorithms have been advanced for the efficient computation of the dft an important tool in digital signal processing is the linear convolution of two finite length signals which often can be implemented very efficiently using the dft
